

Day 7: Netlify and dist folder

Sections:-

- 1) Introduction
- 2) How to create dist folder
- 3) How to use Netlify

1)Introduction:-

Suppose you have completed your Angular project and want to show it to a friend.

One option would be to tell them:

1. Install Node.js.
2. Install Angular.
3. Clone the project from GitHub.
4. Open the project in VS Code.
5. Run `npm install`.
6. Run `ng serve`.

Obviously, nobody wants to do all that just to see your project 😅.

What you really want is to send them a simple link like:

<https://my-project.netlify.app>

and have the project open instantly in their browser.

This is where **Netlify** comes in.

Netlify is a hosting platform that allows you to deploy your web application to the internet. Once deployed, Netlify gives you a URL that anyone can use to access your project from anywhere.

Instead of sharing your source code and asking people to run it on their machines, you share a link and let Netlify serve the application for you.

In simple words:

GitHub stores your code.

Netlify runs your project and makes it accessible through a public URL.

A common workflow is:

Write Code

Push to GitHub

Deploy on Netlify

Share the Netlify Link

This allows anyone to view your project directly from their browser without installing anything.

2) How to create a dist folder:-

When your Angular project is ready, you cannot directly give the whole development project to a hosting platform.

Instead, Angular converts it into a final ready-to-use version.

This is done using:

`ng build`

What does `ng build` do?

It prepares your project for production and creates a final output folder.

What is the `dist` folder?

After running `ng build`, Angular creates a folder called:

dist/

This folder contains the final version of your project that the browser can run.

You can think of it as:

A compressed and ready to use version of your project.

Simple idea

Your Angular project → ng build → dist folder

Why is it important?

When you deploy your project (for example on Netlify):

- You upload the **dist** folder
- Not your full Angular project

Because **dist** is the only part needed to run the app in the browser.

3) How to Use netlify:-

This is how you convert your Angular project into a live link.

Step 1: Build your project

Run this command in your project folder:

`ng build`

This creates a `dist/` folder in your project.

Step 2: Find the dist folder

After build is complete, go inside:

`dist/`

Inside it, you will find your project build folder (final output).

Step 3: Go to Netlify

Open Netlify website:

<https://netlify.com>

Login or sign up (you can use GitHub login).

Step 4: Deploy manually

1. Go to Netlify dashboard.
 2. Find “Add new site”.
 3. Click on **Deploy manually**.
 4. Drag and drop your
`dist/your-project-name` folder.
-

Step 5: Wait for deployment

Netlify will:

- Upload your files
- Process them
- Host your project

This takes a few seconds.

Step 6: Get your link

After deployment, Netlify will give you a live URL like:

`https://random-name.netlify.app`

Step 7: Share your project

Now anyone can open your project using that link without installing anything.

Quick Summary

ng build

dist folder

Netlify drag & drop

Live link generated

THANK YOU.
